The 2048 game logic goes to the package. Everything else that touches the browser is in the app. I wasn't sure whether the score should be in the package or in the app. Because points come from the merge rules,I put the score in the package and put the running total and best score in the app.

Svelte made the code shorter and easier. For example, I don't need repeated code for the nav bar, it is in a single shared layout. The downside is that setting up and deploying are more complicated.

I make sure the versions are sensible, differentiate patch, minor and major changes using the correct numbers. I also specify the version in the app's json file. I document the code update in the changelog.

Many online tutorials use the older Svelte syntax. So in addition to those, I used the course material and asked AI to check my code. I feel I've mastered it. It did make the work easier.

Given more time, I would add an undo button for the game.

I spent around 30-40 hours.

I used AI to assist with writing the README files (excluding the writeup) and to receive recommendations on project structuring and code optimizations.
